## ANSWER NO. 2.

a).

$$f(x_1) = (6+5)(4+1) + (3+5) - (3+2) = 9$$

$$f(x_2) = (8+7) - (1+2) + (6+6) - (0-1) = 23$$

$$f(x_3) = (2+3) - (9+2) + (1+2) - (8+5) = -16$$

$$f(x_4) = (4+1) - (8+5) + (2+0) - (9+4) = -19$$

→  $x_2, x_1, x_3, x_4$

b). One point crossover on  $x_2$  and  $x_1$

$$x_2 = 8712|6601$$

$$x_1 = 6541|3532$$

$$\Rightarrow O_1 = 87123532$$

$$O_2 = 6541660$$

Two point crossover on  $x_1$  and  $x_3$

$$x_1 = 65|4135|32$$

$$\Rightarrow O_3 = 65921232$$

$$x_2 = 23|9212|85$$

$$O_4 = 23413585$$

uniform crossover (random exchanges)

$$x_2 = \underline{8} \underline{7} \underline{1} \underline{2} \underline{6} \underline{6} \underline{0} \underline{1}$$

$$\Rightarrow O_5 = 27126201$$

$$x_3 = \underline{2} \underline{3} \underline{9} \underline{2} \underline{1} \underline{2} \underline{8} \underline{5}$$

$$O_6 = 83921685$$

c). New population:

$$O_1 = 87123532$$

$$O_4 = 23413585$$

$$O_2 = 65416601$$

$$O_5 = 27126201$$

$$O_3 = 65921232$$

$$O_6 = 83921685$$

Applying fitness function:

$$f(O_1) = 15$$

$$f(O_4) = -3$$

$$f(O_2) = 17$$

$$f(O_5) = 13$$

$$f(O_3) = -2$$

$$f(O_6) = -6$$

Overall fitness has improved.

d).

No, the algorithm will never reach the optimal solution without mutation. The optimal solution is  $x_{\text{optimal}} = 99009900$ . If mutation does not occur, then the only way to change genes is by applying the crossover operator.

This means that the first gene in the chromosomes of children can only be either 6, 8, 2 or 4 (i.e. first genes of  $x_1, x_2, x_3$  &  $x_4$ ) and because none of the individuals in the initial population begins with gene 9, the crossover operator alone will never be able to produce an offspring with gene 9 in the beginning.
